Analysis of Lead Concentration in Toronto's Drinking Water from 2014 to 2024*

Renfrew Ao-Ieong

January 22, 2024

The consumption of lead is known to have numerous negative effects on human health. Residents of Toronto are able to provide drinking water samples to Toronto Public Health to test for the amount of lead it contains. Using the Non Regulated Lead Sample dataset from the City of Toronto's Open Data Portal, we found that the median amount of lead in Toronto's drinking water has decreased over the past 11 years. This shows good progress towards eliminating lead from our drinking water entirely.

1 Introduction

Lead is a naturally occurring toxic metal that can be harmful to human health. It can cause neurological, cardiovascular, renal, immunological, reproductive and developmental effects, including developmental neurotoxicity in children. (NCCEH 2022) According to the National Collaborating Centre for Environmental Health (NCCEH), since 1970, Canada has phased out use of lead in gasoline, paint, and other products which has significantly reduced the blood lead levels in Canadians. Currently, the main concern of lead exposure is from drinking water. Presence of lead in drinking water is a serious concern to public health and safety which is why proper precautions are needed to ensure safe drinking water.

Lead can make its way into drinking water when plumbing materials such as pipes, faucets, and fixtures containing lead corrode. In Canada, homes built prior to the 1990s are at risk of using materials containing lead. (Health-Canada 2017) In 2019, Health Canada reduced the Maximum Allowable Concentration (MAC) for lead in drinking water from 10 μ g/L to 5 μ g/L or 0.01 ppm and 0.005 ppm respectively. (NCCEH 2022) This paper will use parts per million (ppm) as the unit of measuring lead concentration in drinking water.

We examined the dataset containing results from testing water samples obtained by residents of Toronto to see if there was a decrease in the lead concentration in drinking water from 2014 to present. We found that there was a decrease in the median lead concentration in Toronto's drinking water since 2014.

The data section will discuss the process of retrieving, summarizing, and finding meaning from the data. The specifics of how the data was cleaned is included in the Appendix.

2 Data

The data used in this paper was retrieved from The City of Toronto's Open Data Portal through the library opendatatoronto (Gelfand 2022). It was then cleaned and analyzed using R, an open source programming language for statistical computing and data visualization (R Core Team 2022) together with the libraries tidyverse (Wickham et al. 2019), dplyr (Wickham et al. 2023), janitor (Firke 2023), knitr (Xie 2023), and ggplot2 (Wickham 2016). The dataset consisted of 12811 individual water samples. Table 1 below shows a sample of the cleaned dataset.

The amount of lead present in water is measured in parts per million (ppm). It is important to note that any higher than 0.005 ppm is not acceptable according to Health Canada. (Health-Canada 2017)

Table 1: Sample of cleaned lead concentration data

Sample ID	Date	Lead Amount (ppm)
1536645	2014-01-01	0.007800
1535456	2014-01-02	0.000110
1536641	2014-01-03	0.000092
1548101	2014-01-06	0.000190
1540991	2014-01-06	0.012000

2.1 Drinking Water Samples

Each sample has a Sample ID, Date which it was obtained, and Lead Amount (ppm) which is the concentration of lead in that water sample in parts per million (ppm). We are interested in the trend of the lead concentration in relation to the year. We have two tables shown below. Table 2 is the mean lead concentration by year while Table 3 is the median lead concentration by year. We partitioned all the water samples by the year it was obtained and calculated the mean and median value of the lead amount.

Table 2: Mean lead concentration of water samples by year

Year	Lead Amount (ppm)
2014	0.0045282
2015	0.0049639
2016	0.0022060
2017	0.0037887
2018	0.0035105
2019	0.0054675
2020	0.0267115
2021	0.0011348
2022	0.0095108
2023	0.0054486
2024	0.0001450

Table 3: Median lead concentration of water samples by year

Year	Lead Amount (ppm)
2014	0.0003345
2015	0.0003255
2016	0.0001980
2017	0.0001760

Year	Lead Amount (ppm)
2018	0.0001365
2019	0.0001385
2020	0.0000939
2021	0.0001400
2022	0.0001100
2023	0.0002455
2024	0.0001450

2.2 Mean vs. Median Lead Concentration by Year

Plotting the mean and median lead concentration by year, we can see that there has not been a significant change in the mean concentration of lead in drinking water since 2014. On the other hand there has been a decreasing trend in the median concentration of lead in drinking water since 2014. Figure 1 does not show a significant trend in either direction. This is because of outliers that skew the results. For example, in 2020 the mean concentration was 0.0267115 ppm (More than 5 times the MAC). This was due to a water sample that had a concentration of 8.44 ppm which had a large effect on the mean due to the other values being small numbers such as 0.0005. Figure 2 which is the median lead concentration by year paints a better overall picture of the water quality in Toronto as the median is not as sensitive to outliers as the mean is.

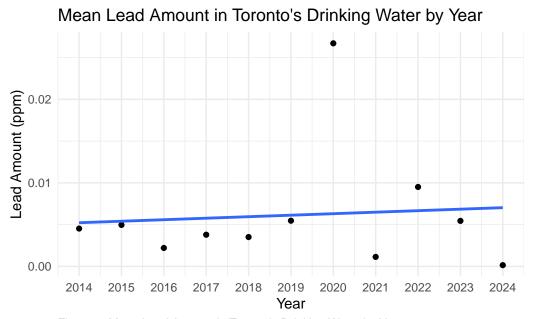

Figure 1: Mean Lead Amount in Toronto's Drinking Water by Year

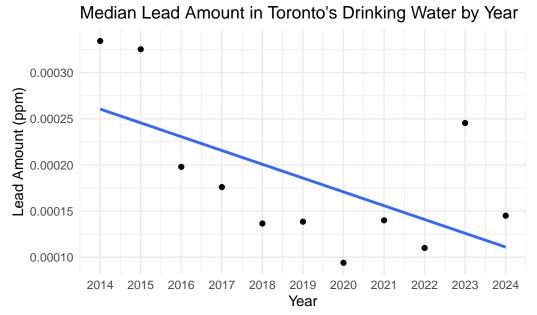

Figure 2: Median Lead Amount in Toronto's Drinking Water by Year

2.3 City of Toronto Corrosion Control Program

To prevent the contamination of lead into tap water due to corrosion, the City of Toronto implemented the Corrosion Control Program which aimed to prevent corrosion of pipes and plumbing fixtures by adding phosphate to the drinking water treatment process. (Toronto 2022a) This took effect in 2014 and Toronto Water estimated that it would take up to 2 years for a protective coating to form inside all pipes. As we can see from Figure 2, the data does not seem to show a decline from the year 2014 to 2015. However, from 2015 to 2016 the median lead concentration decreased from 0.0003255 to 0.0001980 ppm which aligns with the 2 year period in which the phosphate protective coating needed to form. Since then, the median lead amount of a particular year never reached as high as 2014 levels. From the data, there is evidence to support the fact that the implementation of the Corrosion Control Program had a noticeable impact on the water quality in Toronto.

2.4 Regulated vs. Non Regulated Testing

It is important to note that the water samples in this dataset was collected from a non-regulated program. This means that the samples were voluntarily submitted by residents of Toronto. This may lead to sampling bias as someone who is living in an older home with a higher possibility of containing lead plubmbing materials may be more likely to test their drinking

water. Another issue with voluntary samples is that the sample may be tampered with since there are no checks to verify where the water came from.

The City of Toronto currently collects and analyzes water samples as a part of the Corrosion Control Program. (Toronto 2022b) This regulated testing program requires taking samples throughout the year from at least 55 residential and non-residential tap locations as well as 10 distribution system locations. In 2022, the maximum measurement for residential and non-residential locations was 0.00386 ppm, the minimum was less than 0.00005 ppm, and the average was 0.0005 ppm. This was a decrease compared to 2017 where they measured a maximum of 0.0732 ppm, minimum of less than 0.00005 ppm, and an average of 0.0028 ppm. Prior to the Corrosion Control Program, samples taken from 2007-2008 recorded a maximum of 0.014 ppm, minimum of less than 0.00051 ppm and an average of 0.0038 ppm.

In both regulated and non regulated testing, the data shows an improvement in water quality when compared to the past results.

4 Appendix

4.1 Data Cleaning

The steps taken to obtain this cleaned data is as follows. First, we used the function clean_names from the janitor package (Firke 2023) to give us column names that are unique and only consist of underscores, numbers, and letters. Next, we converted the lead_amount_ppm column from character type to numeric type. However, there were 2995 samples that contained a lead amount of <0.00005 which can not be converted directly to numeric type as it contains the < character. Thus, we chose to convert all samples with that amount to 0.00005. Then, we chose to discard the x_id and partial_postal_code columns because those will not be used for our purposes.
